1. Complete local states
One member retains every parameter and its membership
2. Member lattices
Preference chains define joins, meets and cover edges
3. Structural collaboration
Use isomorphisms, embeddings or a common-lattice pullback
4. Feasibility and support
Retain compatible observed states without inventing support
5. Separate order audits
Test ambient closure and internal least and greatest bounds
6. Exact path optimization
Use additive or length-indexed dynamic programming
7. Empirical validation
Freeze training choices; examine holdout and full refits
8. Scope of the result
An optimal ordered profile is not a causal operating policy
